

**SPEAKER 1:** There's no doubt that our patients with diabetes and heart disease are at a very high risk of having a subsequent event. In fact, the recent guidelines from the American College of Endocrinology have actually, for the first time, come up with a new category of risk called extreme risk, and they recommend an LDL less than 55 in these patients. And I think it's totally appropriate, because if you look at their likelihood of having an event, it continues to be twice as high as people without diabetes. So this is certainly a population in which we want to get their LDL as low as we can.
