

**SPEAKER 1:** The treatment of cutaneous T-cell lymphoma is stage based. There are stages 1 to 4. Stages 1 to 2A are the early stages, and these tend to be treated with skin directed therapy. So that's creams or phototherapy. The advanced stages, which is 2 beta 4, often need systemic treatments. And these are typically immune modifiers first, such as photopheresis. Photopheresis is preferred in patients with erythrodermic disease. That means their skin is red all over, and those that have blood involvement.
