

SPEAKER 1: Photopheresis can be used on its own, but because of its very safe profile, it can also be combined with other anti-CTCL drugs. Typically, this is bexarotene and an interferon, and these may be combined all three together, which is sometimes referred to as triple therapy. The patients could start on all three treatments, and as their disease improves, they may stop the interferon or bexarotene. Photopheresis sometimes is prolonged, and can be given for many years if the patient is responding.
