

The dosing for adults is very straightforward. It comes in 300 milligram per syringe. And for adults, you do two of those, so 600 milligrams is a loading dose. And then every two weeks, it's 300 milligrams, one of those syringes subcutaneously ongoing.

For the adolescent group, 12 to 17 years, there's actually a slightly different dosing approach, depending on their weight. If they're over 60 kilograms, we do just as we do for adults-- 300 times 2 to load, and then 300 once every two weeks to maintain. If they're under 60 kilograms, then, actually, they make a smaller syringe, a 200 milligram syringe. And we just mirror what we do with the 300.

So again, two of those to load, which would be 400 milligrams, and then one 200 milligram syringe every two weeks going forward. So that's a little bit of nuance with the dosing, but really, it's just that one weight cut-off at 60 kilos. We just want to ask the patient where they stand, or perhaps weigh them in clinic that day.
