

Well, if you look at a set of Parkinson's patients, I say this in clinic every day, I say, well, you're one of those compliant Parkinson's patients. So it's a funny line, I know. But whenever I say that, if you look at how patients dose themselves, we used to think patients with Parkinson's were very compliant with both the timing and taking the doses of the medication.

But sometimes folks are busy and life gets in the way, and you screw up your regimen. And you wind up being off or stiff and slow, and those things happen to patients over time. But for the majority of patients, they're fairly compliant with their timing because their body needs to leave it open to keep moving well.

But the classic patient who is a good patient for the fractionated scored levodopa preparation called Divi is the patient who wants a very tight control of their Parkinson's daily course, who needs to have on time, as best as possible, with lower amount of dyskinesia, hopefully. And they can titrate their dose perfectly to where they know their body is.

I don't live in my patients Parkinson's bodies. So I don't know exactly where they are at a given time, at a given situation. And so having the ability to take a little bit of levodopa or a lot of levodopa, as needed, is commonly done by patients.

They don't always tell us, but they may take a little extra levodopa if they've got an event going on that they have to be less tremulous or less slow. And Divi and other medications can help you titrate to what you need to do during the day. So that's one patient population I think that could really benefit, those who really need tight control with their on/off situation during the day.
